ABSTRACT	253
METHOD	253
INTRODUCTION	253
RESULTS	253
GENERAL SURVEY OF ART IN GERMANY	
Outcome of ART 2010	256
Number of IVF-centres 1982–2010	256
Number of treatment cycles 1982–2010 (plausible cycles)	256
Number of treatment cycles 2010 (prospective cycles)	257
Number of cycles with ovum pick up (OPU) 2010	257
Statistics in short 2010 for IVF, ICSI and IVF/ICSI	257
D·I·R-statistics in short 2010	258
D·I·R-statistics in short 2009 (update to annual 2009)	259
Clinical pregnancies, miscarriages, ectopic pregnancies and stillbirths 2009	260
Multiple deliveries 2009	260
Deliveries as a function of the number of embryos transferred and age groups (2000–2009)	261
Deliveries as a function of the number of embryos transferred – IVF, ICSI, cryo-transfer (2000–2009)	261
Fertilisation rate per oocyte IVF and ICSI 2010	262
Distribution of indications for IVF and ICSI 2010	262
OUTCOME OF IVF, ICSI AND CRYO-TRANSFER	
Outcome of IVF, ICSI and cryo-transfer 2010	263
Outcome as a function of woman's age – IVF 2010	264
Outcome as a function of woman's age – ICSI 2010	264
Clin. Preg. rate as a function of the number of embryos transferred and age groups 2010	265
Clin. Preg. rate as a function of the embryo quality IVF, ICSI, IVF/ICSI 2010	265
Clin. Preg. rate as a function of the embryo quality, cryo-transfer 2010	266
Miscarriage rates as a function of woman's age and number of embryos transferred 2010	266
Clinical pregnancy-rate as a function of the stimulation protocol – IVF, ICSI 2010	267
Clinical pregnancy rate as a function of the number of oocytes inseminated/ microinjected – IVF, ICSI (1997–2010)	268

Contents

Contents

Clinical pregnancy rate as a function of the duration of stimulation using GnRH-agonists or -antagonists – IVF, ICSI (2000–2010)	268
Number of treatment cycles per patient as a function of woman's age – IVF, ICSI, IVF/ICSI (2000–2010)	269
Duration of childlessness at the time of first treatment – IVF, ICSI, IVF/ICSI (1997–2010)	269
Average age of women and men – IVF, ICSI, IVF/ICSI (1997–2010)	270
Clinical pregnancy rate as a function of the month in which the embryo-transfer was performed IVF, ICSI (2000–2010)	270
CHILDREN BORN	
All children born (1997–2010)	271
Childrens birth weight (bw) and week of gestation (wg) 2009 (singletons, twins, triplets)	272
OHSS AND COMPLICATIONS	
Complications as a function of ovum pick up 2010	273
OHSS as a function of the stimulation protocol – IVF, ICSI, IVF/ICSI 2010	273
QUALITY OF THE CENTRES OUTCOME	
Percentage of centre hopping compared with clin. PR/ET between the largest 100 centres (1997–2010)	274
EPILOGUE	
ACKNOWLEDGEMENT	
LIST OF CENTRES PARTICIPATING IN D-I-R

Abstract: The German IVF-Registry (Deutsches IVF-Register, D-I-R) was established in 1982. Its main objective, from the beginning, was to lend transparency and openness to the newly established infertility treatment options.

By 1996 electronic data collection was implemented, allowing the online check for data completeness and plausibility as well as ensuring prospectivity.

Since 1997, data entry has to be performed electronically. From 1998, participating in the German IVF-Registry has become mandatory by decree of the German Medical Association.

By the year 2010, the registry comprised 124 centres, with all 124 submitting their data to D-I-R: 77,904 treatment cycles were reported in 2010; 75,928 datasets are plausible, and 63,422 fulfil prospectivity. 50,583 oocyte retrievals led to an IVF or ICSI treatment, and in 46,419 of these “fresh” cycles, an embryo transfer (ET) was performed. In addition to these “fresh” cycles, 17,929 embryo transfers with cryopreserved thawed pro-nucleus-stage oocytes were recorded.

In 2010, the clinical pregnancy rate for IVF is 29.5% and for ICSI 28.4%. Generally we observe that in the data-collection-year the outcome of about 40% of all reported pregnancies is unclear. One year later this figure decreases to about 12.5–15%. From 1997 to 2010, a dramatic reduction of triplets results from the 20% reduction of the number of embryos transferred. Across all years, the miscarriage rate after cryopreservation has remained significantly higher compared with fresh cycles (23.4% vs 18.8%). More than one million cycles have been collected since the registry’s establishment in 1982 and the births of 156,809 children have been reported to D-I-R since 1997. **J Reproduktionsmed Endokrinol 2011; 8 (4): 253–80.**

■ Method (Statistics)

Exclusively descriptive statistics were used in the yearbook. These statistics have the aim of representing a large set of data and tables clearly. Graphics and tables are primarily prepared with average values, medians, box-charts etc. to subsume the data stocks. This method is usual at the representation of extensive data to receive a reasonable summary.

■ Introduction

The German IVF-Registry (Deutsches IVF-Register, D-I-R) was established in 1982. When the first IVF-baby was born in Germany that year, 5 university centres for the first time decided to publish their results. The idea behind this endeavour was to lend transparency to this new infertility treatment modality which was in the centre of public dispute at that time.

Although the engagement was on a voluntary basis at first, the number of participants increased as rapidly as the number of IVF centres: from 53 centres in 1990 to 71 in 1996.

The registry was completely reorganised in 1996. Up to then all centres had reported their activities by a written summary once a year or by using a d-base

software solution (IVF-C, Medis). With RecDate, a Filemaker®-based, industry-sponsored software, electronic data collection was introduced in 1996.

Reporting cycle by cycle not only allowed for the control of plausibility of the data input but prospective data collection had become a reality. To enable prospectivity, each cycle has to be entered into the system within the first eight days of stimulation. Starting in 1997, only electronic data collection was supported. In 1998, the participation in the registry became mandatory by decree of the German Medical Association. By the year 2000 the number of centres had increased to 102; by 2010 124 were exporting their data to the registry.

By 2003, the registry had created its own data collection software, DIRpro, a SQL database. The industry-independent data collection was now an option for the centres. DIRpro is the electronic questionnaire for the registry; RecDate and especially its update RecDate advance – now SQL-based as well – fulfil all requirements concerning documentation in an IVF centre. To meet the widening scope of data collection, DLL, a special interface was developed by the registry. The DLL-interface allows the application of any other software for the data collection, provided it meets the D-I-R

criteria. DLL performs an online check for plausibility and prospectivity with direct and immediate feedback to the centre.

Since 1982, data on more than 1.1 million treatment cycles have been collected by the Deutsches IVF-Register, mostly of excellent data quality. On account of this, D-I-R has become a highly respected and excellent instrument for quality assurance in the field of reproductive medicine.

Since 1996, an annual report has been published in German; starting in 2010 we have added an English version. This year we celebrate the 15th anniversary of our yearbook: 15 years of classical statistics as well as new considerations based on statistics drawn from our huge database.

■ Results

For the past 15 years, the annual report has been reserved for the description of the situation in the reporting year and for general information about developments since 1982.

It is absolutely necessary to point out the importance of differentiating between “all cycles”, “plausible cycles”, and “prospectively collected cycles”.

In every graph or table the data pack is indicated respectively (p. 256). Page 257 demonstrates the development of the number of those oocyte retrievals leading to IVF or ICSI treatments from the very beginning in 1982.

Political impacts are very clearly visible: while in the year 2000 only ICSI was affected, in 2004 both IVF and ICSI took deep slumps.

The so-called “data tree” on page 258 gives a condensed overview of all recorded cycles in Germany in the year 2010. Due to the early submission deadline – August 10, 2011 – the outcome of reported pregnancies is not available in 35.2% to 46.6% of the cycles.

One year later, the updated tree (p. 259 condensed report 2009) illustrates a reduction of missing data from 12.5–15%.

The outcome of reported clinical pregnancies and data about multiple pregnancies therefore are always reported for the preceding year (p. 260, 261). The shaded background in charts and tables indicates that data from preceding years (excluding the actual year) are presented. The following gives an overview of the fate of every aspirated oocyte in the year 2010. While the mean number of transferred embryos has decreased about 20% in fresh cycles, and 13% in freeze-thawed-cycles this did not result in a reduction in the number of children born per ET or per delivery (figures for 2010 are not representative; see above). Among the female indications for an IVF treatment, tubal infertility shows the highest incidence. Reduced sperm quality – as expected – triggers most of the ICSI treatments (p. 262).

Page 263 reveals the history of treatment from oocyte-retrieval to implantation and delivery for all treatment-options. The aim is to show how successful the treatments in Germany are. In the figures on page 264 treatment results in their respective age groups for pregnancies and abortion rate are presented. Highlighted light blue in the table shows the results for patients with good prognosis (good ovarian response). On page 265 is now further specify the number of embryos transferred in the respective age groups. It shows a clear trend that has been trans-

ferred, especially in the age groups < 35 years only in exceptional cases (< 11%) more than 2 embryos in the “fresh cycles” to avoid higher grade multiple pregnancies.

Only in the frozen-thawed cycles, the transfer with more than 2 embryos in women < 35 years is slightly higher (20%) because the overall risk of multiple pregnancies in frozen-thawed cycles is pretty much lower (compare figure p. 261 below).

The figure below shows the increasing probability of success for each age group with the presence of one or more good quality embryos. A overall survey shows the next table with number of treatments in the presence of one or more good quality embryos page 266. In consideration of miscarriage, the table page 266 below shows the increase in abortions based on the number of embryos per age group divided into fresh and frozen thawed cycles.

As in previous yearbooks are on page 267 the success probabilities of each stimulation substance divided in groups of the combination with GnRH releasing hormones (agonist/antagonist) with gonadotropins (urinary/recombinant) in IVF and ICSI treatments.

The first graph on page 268 gives the clinical pregnancy rate per embryo transfer for the number of oocytes inseminated (conventional IVF) or micro-injected (ICSI).

As expected, there is a clear correlation to the clinical pregnancy rate depending on the number of inseminated or injected oocytes.

According to the German Embryo Protection Act not more than three embryos are allowed to be transferred in one cycle. So for the full chance in a fresh cycle at least 9 oocytes should be available. If more, all oocytes will be treated and used in future cycles. Thereby, cumulative pregnancy rates will increase.

The second graph on this page gives the clinical pregnancy rate depending on the days of ovarian stimulation in GnRH-agonist and GnRH-antagonist protocols for the last decade.

The highest clinical pregnancy rate by embryo transfer will be achieved with stimulation of 8–12 days.

This is not astonishing as in cycles with a very short stimulation (accelerated follicular maturation) or long stimulation (delayed follicular maturation) the underlying ovarian pathology reduces oocyte quality and clinical pregnancy rate. It is very interesting, that obviously there is a significant higher clinical pregnancy rate per embryo transfer after stimulation in GnRH-agonist than in GnRH-antagonist protocols. But this result may be biased by patient selection in preferring antagonist stimulations preferentially in patients with expected low response.

The first graph on page 269 gives the number of fresh cycles for the different age groups. With age there is a significant increase in the average number of fresh treatments per woman. The age was recorded at the time of the first cycle. This may explain the drop after 38 because in Germany the reimbursement of treatment costs stops with the age of 40 for the woman. So often a second or third fresh attempt was not possible.

The second graph on page 269 shows the duration of involuntary childlessness before the first IVF cycle. From 1997 onwards there was a significant decrease towards earlier treatment. In the last years we have an average of 3–4 years involuntary childlessness before entering an IVF program. This accounts for the severe subfertility of couples undergoing IVF in Germany with only a very low chance of spontaneous conception left.

The first graph on page 270 shows the mean age of men and women starting with IVF. There is an increasing age over the last years with a significant step after 2004 with changes in the reimbursement. In the mean time the mean age of women treated reached nearly 35 years of age.

The second graph gives the clinical pregnancy rate per embryo transfer for the calendar months of embryo transfers in the last 10 years. There seems to be no significant differences in between the different months. So speculative effects of seasonal differences, holiday-months

or other can not be concluded from the results of our huge database.

The two tables on page 271 demonstrate the number of singletons and multiples of all born children in a period of 14 years.

Numbers given in brackets indicate the amount of live born children.

Prospective and non-prospective cycles had been analysed. Prospective cycles are entered in the computer system with a maximum of 8 days after the first day of controlled ovarian hyperstimulation.

The four graphs and three tables on page 272 demonstrate birth weight depending on gestational week for singletons and multiples.

The graph and tables on page 273 focus on side effects and severe complications during IVF/ICSI procedure. The total rate of complication is low (0.7%).

One severe iatrogenic complication is the ovarian hyperstimulation syndrome. The table demonstrates the rate of OHSS depending on different pharmaceutical protocols.

Only severe cases are documented.

■ Epilogue – International Cross Comparison of ART-Results

Cumulative ART success rates (conventional IVF, IVF/ICSI and cryocycles) are much better indicators of quality and success in IVF-programs and allow comparisons between different centres to figure out possible advantages or disadvantages of national IVF policies (restrictions and liberations) and individual centre's strategies. Cumulative success rates are also important figures for basic economic and political considerations of ART reimbursement.

The most national indices have not published cumulative success rates so far, because of the inhomogeneous structure of data and because of anonymity of participating centres. Recently, cumulative live birth rates after ART were published by a single centre in the USA including all ART cycles [1]. To compare ART results we exemplarily calculated cumula-

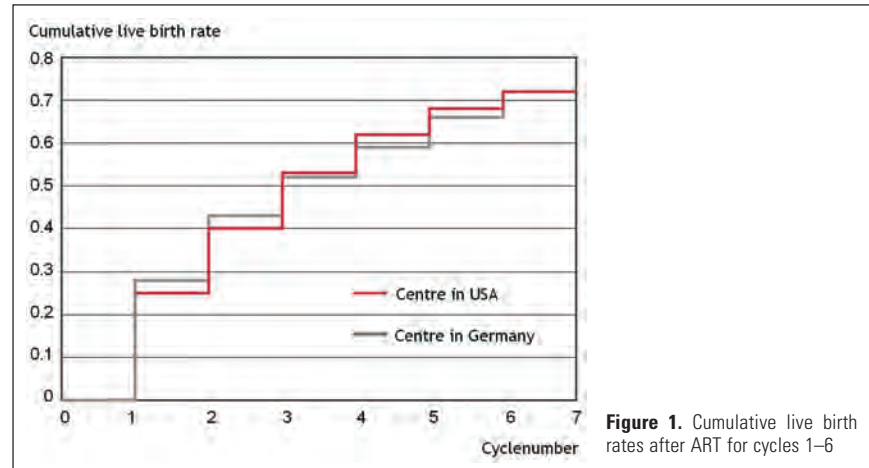

Figure 1. Cumulative live birth rates after ART for cycles 1–6

tive live birth rates of a single centre in Germany [2] according to the assumptions of Kaplan-Meier.

We compared 14,248 ART cycles in 6164 patients in the US centre (2000–2004) with 8,848 Cycles in 3,394 patients in the German centre (1998–2007). There was a maximum of 10 cycles in one individual women in the US centre and 22 cycles in the German centre. 35% of the ART cycles in the US centre were ICSI versus 70% in Germany. According to the strict interpretation of the German Embryo Protection Act the culture of more than three pronuclears was prohibited because only as many pronuclears as were planned to be transferred in one cycle were allowed to be cultured. Pronuclears that were not intended for implantation in one cycle had to be discarded or to be cryopreserved. As a consequence a prolonged culture with a selection of the best embryos and embryo cryopreservation was not possible. In cycles 1–6 3,126 live births were recorded in the US centre versus 1,705 live births in the German Centre (Fig. 1). There were 27,3% twin births in the US centre and 19,7% in den German centre. In the US centre there were 8 quadruplets, no in Germany.

After 6 treatment cycles the cumulative live birth rate reached 72% in both centres. Stratifying the results for the patient's age we see comparable results up to a patient's age of 40 years with 86% in patients < 35 years of age in both centres.

Obviously, complete the different treatment strategies and completely different national regulations led to the same re-

sult: an overall cumulative live birth rate of 72% after 6 treatment cycles.

Very recently another study of a single centre in Spain was published on cumulative live birth rates per total number of embryos transferred [3]. Comparing their results to the German centre we again find comparable cumulative live birth rates over the total number of embryo transferred. So again, different treatment strategies, different national regulations lead to the same cumulative ART success rates which reach natural fertility rates but can not exceed them.

■ Acknowledgement

Our sincere gratitude goes out to all the participating centres. For the past 15 years, the teams in those centres – the physicians, embryologists, assistant medical technicians as well as all of the other medical staff – have diligently performed the data collection. Their effort and dedication are the foundation for D·I·R's enormous success. Our gratitude also goes out to the staff at the Medical Association of Schleswig-Holstein for 15 years of data evaluation. We would also like to thank all of those assisting us in publishing the English version of the yearbook again.

Outcome of ART 2010

centres for IVF-, ICSI-, GIFT- und cryo-transfer treatments

Participating IVF centres	n = 124
Data received until deadline (10.08.2011)	n = 124
Documented treatment cycles	n = 77,904 (100.00 %)
Plausibel	n = 75,928 (97.46 %)
Prospective (all cycles)	n = 63,422 (83.53 %)
Prospective (IVF, ICSI, IVF/ICSI)	n = 41,102 (81.26 %)
Number of treated women*	n = 47.159
Treatment cycles per women (mean)	1,65

*) Base quantity: all women with specified age; implausible treatment cycles are counted also.

		19.78 ²		19.98 ²		23.64 ²		12.43 ²

Prospectively and retrospectively collected data were used.

*) Number of cycles, in which an induced abortion/fetal reduction was documented. Detailed data cannot be given. Number of embryos are given in brackets.

**) Number of dead newborns corresponding to the number of children

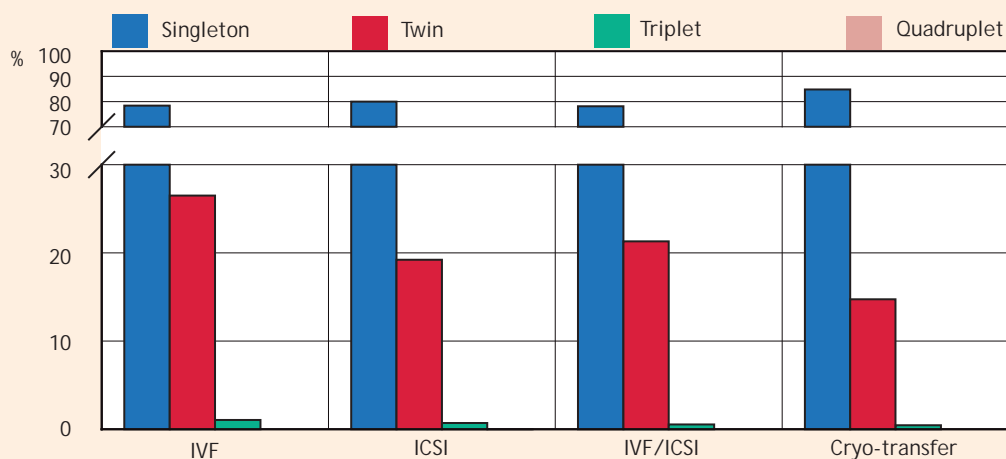

***) Number of deliveries in correlation to the number of treated cycles given in percent

1) Total number of treatment cycles reduced for those cycles with unknown pregnancy outcome

2) For cycles with unknown pregnancy outcome the probable rate for deliveries was calculated (delivery per pregnancy) and added to the reported number of deliveries

Delivery rate/transfer for patients with 2 embryos transferred and at least 2 2PN stages in abundance: IVF 24,33 %, ICSI 23,98 %, IVF/ICSI 27,39 %

Multiple deliveries 2009

Prospectively and retrospectively collected data were used.

*) e. g. U-FSH and hMG, Clomifen/rec-FSH, Clomifen/hMG etc.

Only prospectively collected data were used.

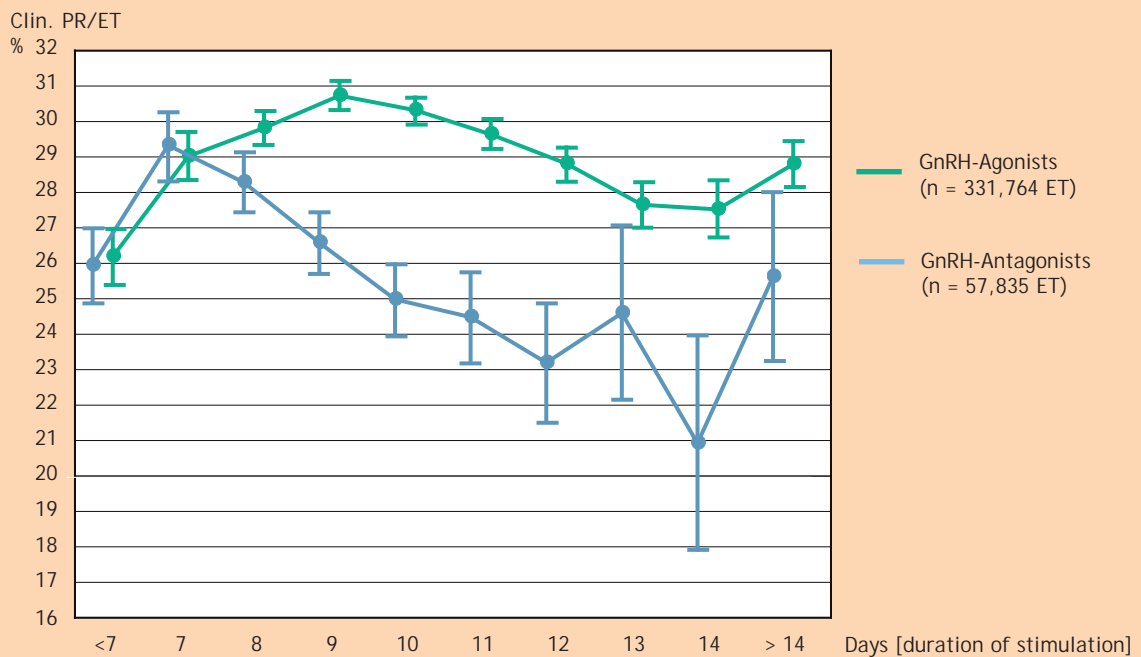

Clinical pregnancy rate as a function of the number of oocytes inseminated/microinjected 1997 - 2010 IVF, ICSI

Only treatment cycles with a minimum of 5 oocytes collected during ovum pickup are analysed.

Prospectively and retrospectively collected data were used.

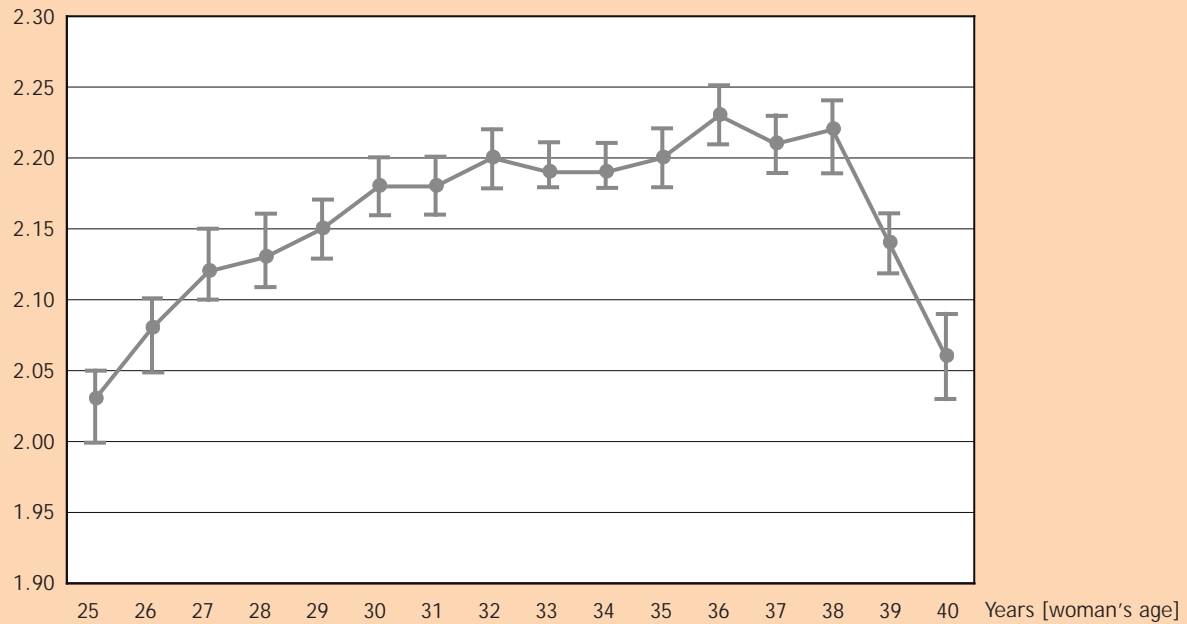

Clinical pregnancy rate as a function of the duration of stimulation using GnRH-agonists or -antagonists, 2000 - 2010 IVF, ICSI

Prospectively and retrospectively collected data were used.

Number of treatment cycles per patient as a function of woman's age 2000 - 2010 IVF, ICSI, IVF/ICSI

n [Treatment cycles per patient]

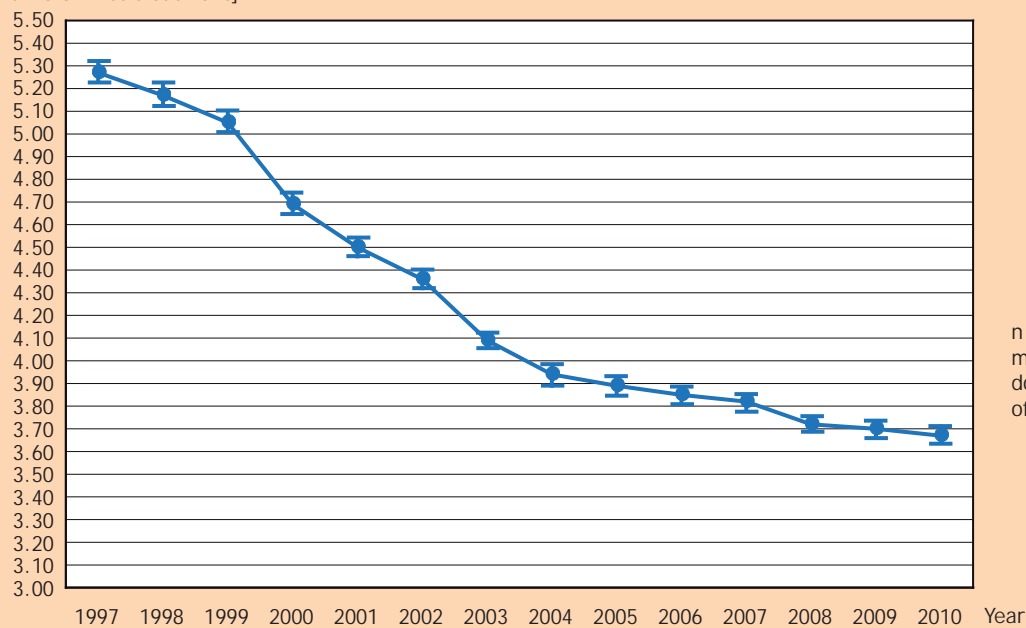

n = 292,209 cycles with plausible age documentation

Prospectively and retrospectively collected data were used.

Duration of childlessness at the time of first treatment

1997 - 2010 IVF, ICSI, IVF/ICSI

Years [Duration of childlessness at the time of first treatment]

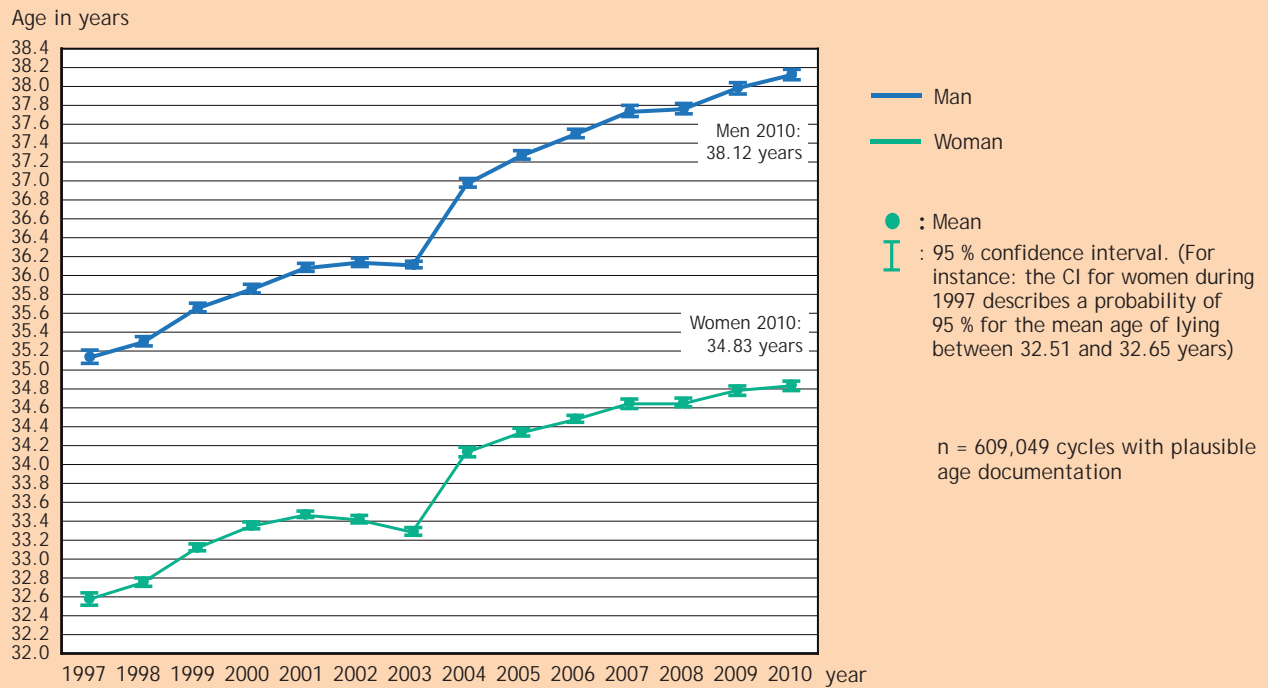

n = 305,981 first treatment cycles with documented duration of childlessness

Prospectively and retrospectively collected data were used.

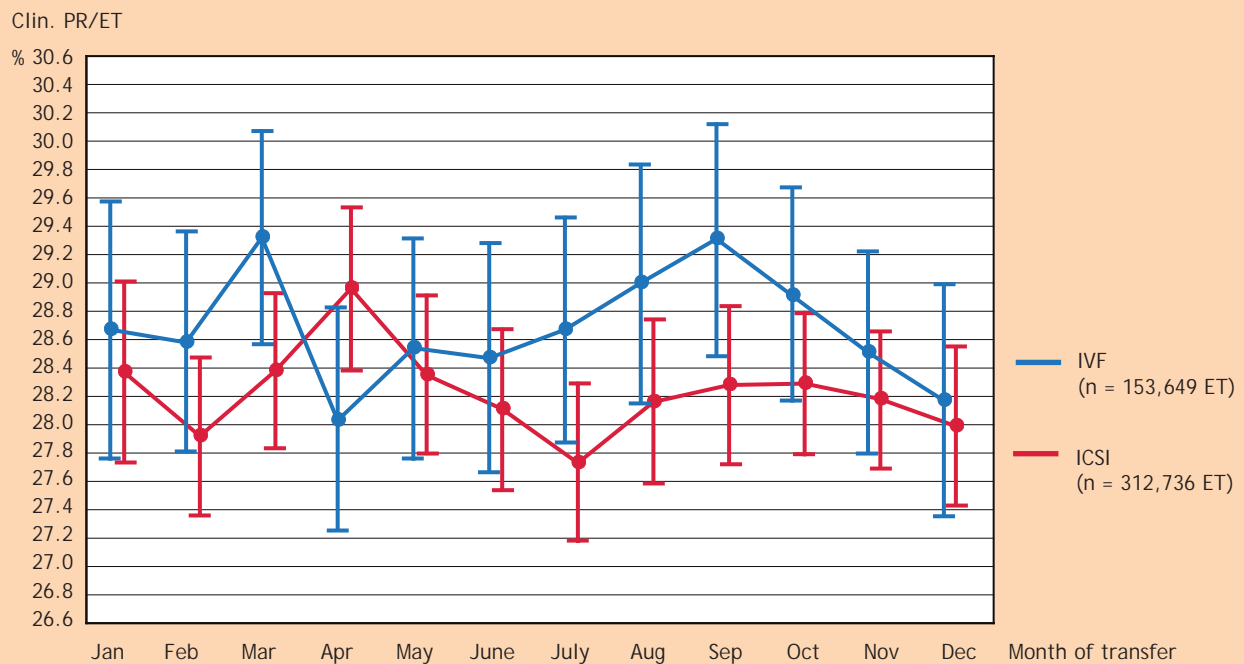

Average age of women and men

1997 - 2010 - IVF, ICSI, IVF/ICSI

Prospectively and retrospectively collected data were used.

Clinical pregnancy rate as a function of the month in which the embryotransfer was performed, 2000 - 2010 - IVF, ICSI

Prospectively and retrospectively collected data were used.

All children born 1997 - 2010

prospective und retrospective data

IVF, ICSI, IVF/ICSI

Total	41,102	100.00	9.39	93	0.23

Only prospectively collected data were used.

Percentage of centres hopping compared with clin. PR/ET between the largest 100 centres 1997 - 2010

Base: the largest 100 centres with at least 750 women and number of treatment cycles > 2,000. n = 328,980 women

● PR/ET in %

— Definition "center hopping":

"Centre hopping": a couple changes the fertility centre after at least one treatment cycle.

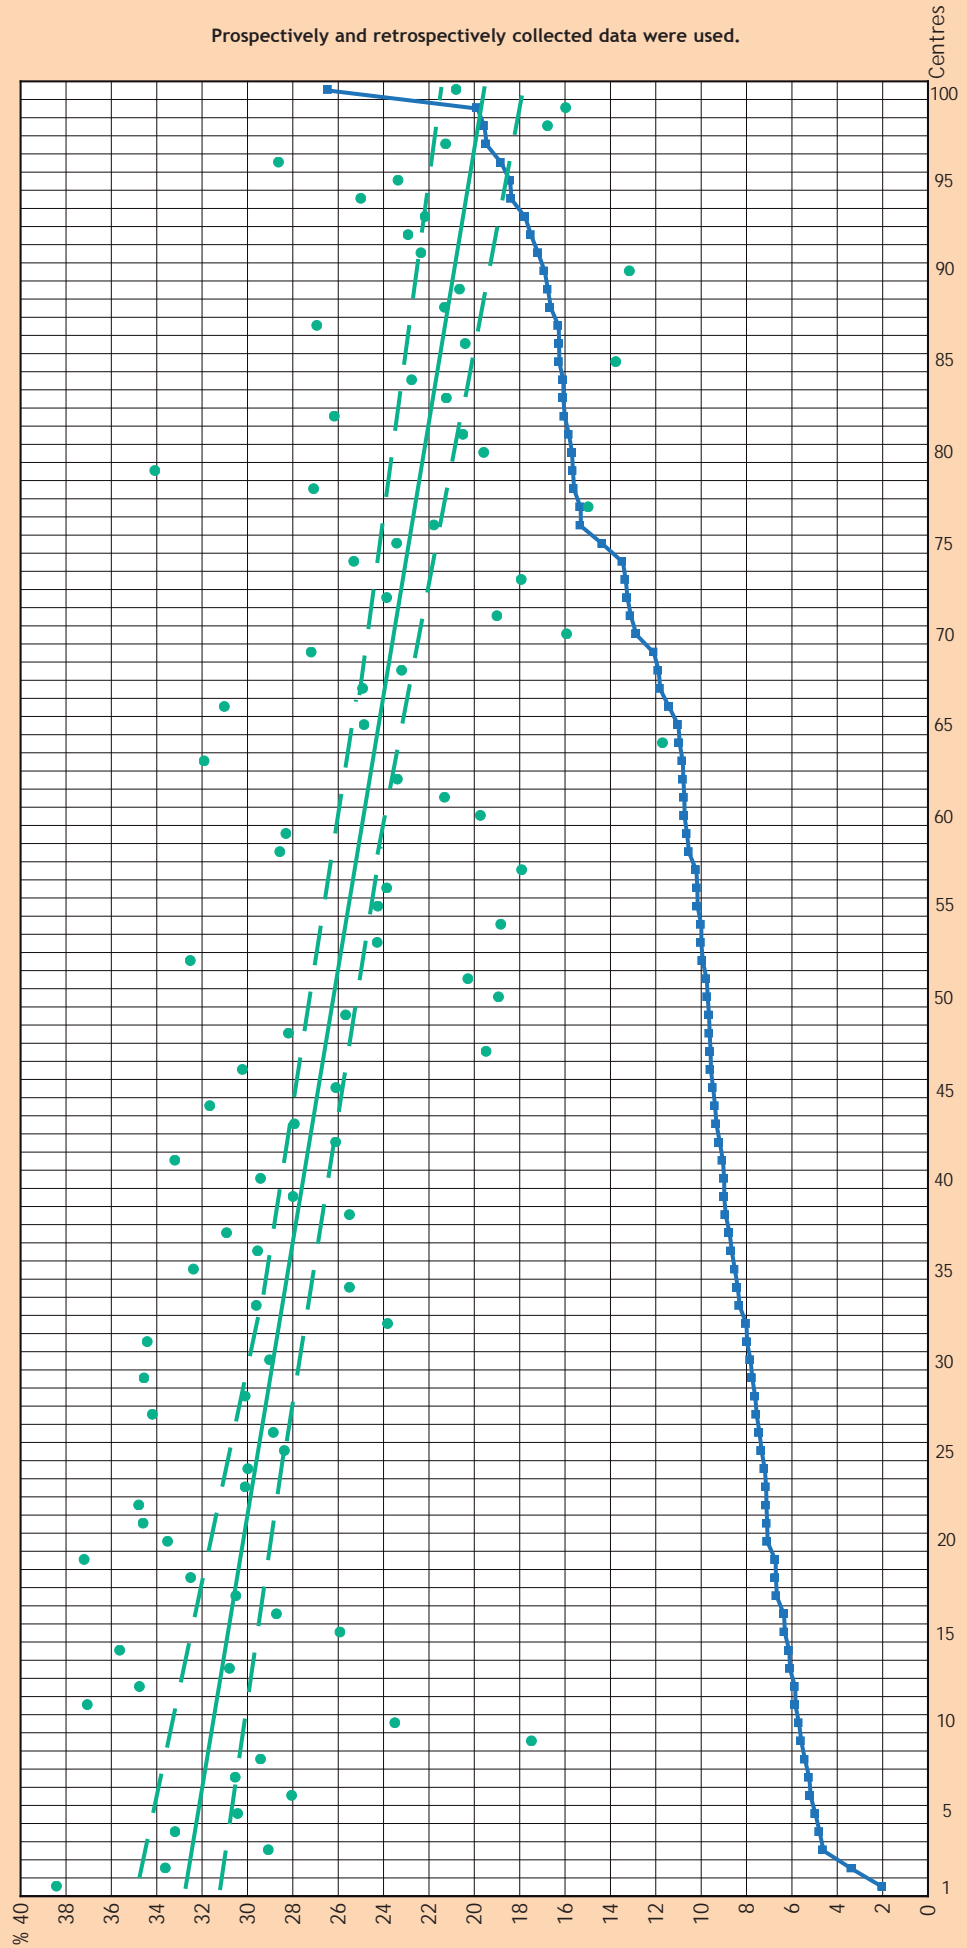

■ Irreversible encryption.

— Interpretation of results:

The change-rate seems to rise in correlation to decreasing pregnancy-rates

— The linear function is a method positioning a best-fit line in a scatter plot so that the mean square aviation of the data points is minimized by this function.

The straight line indicates the linear regression function of the single values of the particular item.

Centres reporting to the German IVF Registry in 2010
